Trace
for Adobe Premiere Pro

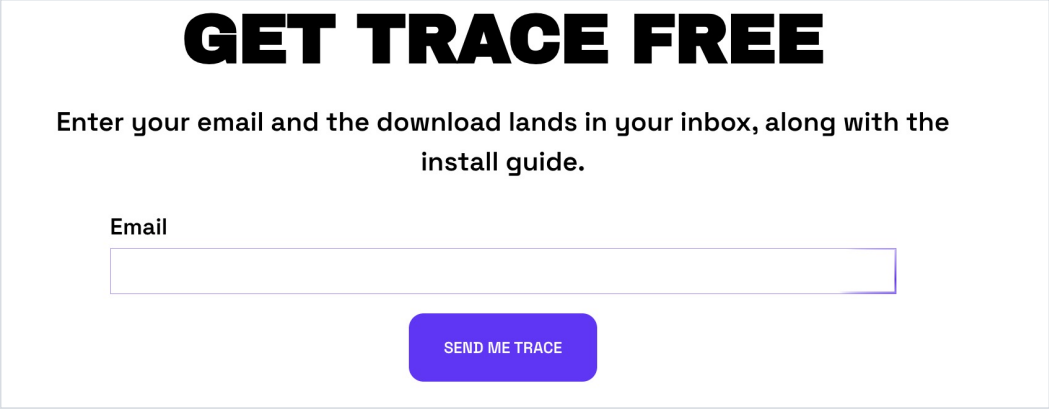

Installing Trace

Free. Two steps, about a minute.

Pick one clip. See every place it's used across your entire project — then select every instance at once.

1 Get the link, then double-click the file

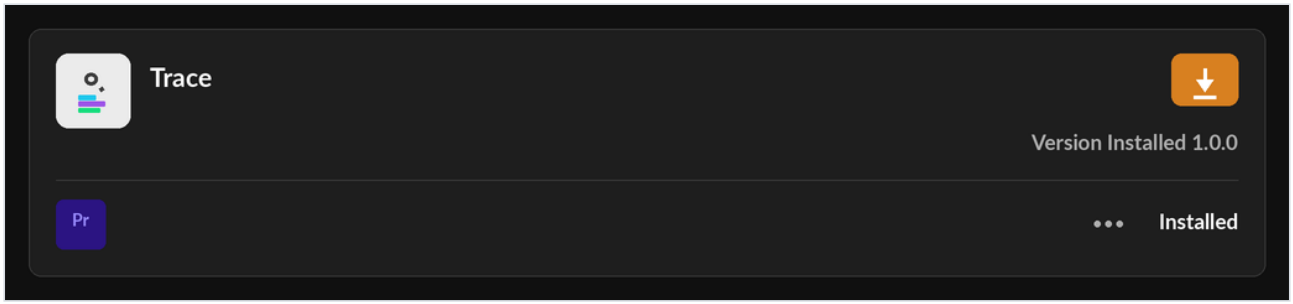

Trace is free. Enter your email at nkcourses.co.uk/trace and the download link arrives in your inbox with this guide. Open it, download Trace.ccx and double-click it — Creative Cloud Desktop installs it for you. There is no licence key and nothing to sign in to. Nothing arrived? Check spam, then email support@nkcourses.co.uk and I will send it straight over.

nkcourses.co.uk/trace — enter your email and the link arrives in your inbox

2 Restart Premiere Pro

Quit Premiere and open it again. Premiere only looks for new panels at startup. You need Premiere Pro 25.6 or newer — check under Premiere Pro > About Premiere Pro.

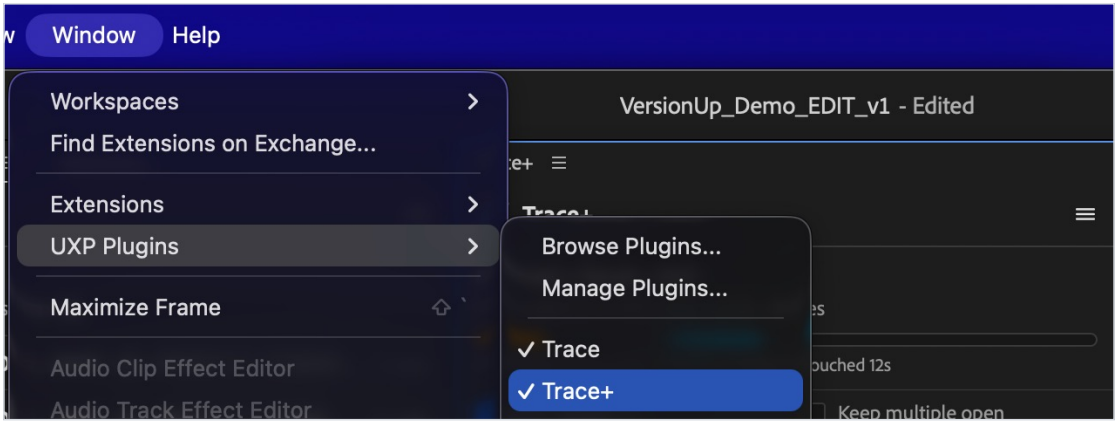

Creative Cloud Desktop says Installed — now restart Premiere

3 Open the panel

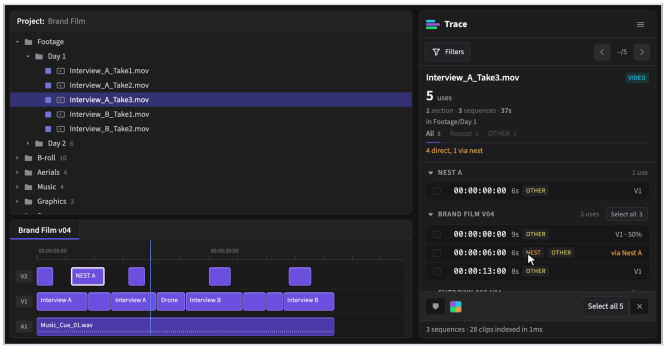

In Premiere, go to Window > UXP Plugins > Trace. Not Window > Extensions — that is the old CEP menu, and Trace is a UXP panel. Drag it wherever you like: down the side, under the timeline, or floating.

Window > UXP Plugins > Trace. (Trace+ is the paid panel — it only appears if you have it)

4 Click a clip

That is the whole gesture. Select any clip in the Project panel and Trace lists every place it is used, in every sequence, with a timecode for each. Press Select all to select every instance in a sequence at once — the one thing Premiere cannot do for you.

Click a clip in the Project panel. That is the whole gesture.

Every gesture, on one row of the list

Click
Go there — the sequence opens and the playhead lands on that use.

Cmd-click (Ctrl on Windows), or the tick box
Add that use to the timeline selection. A selection cannot span two sequences, so ticking one in a different sequence replaces the rest, and the panel says so.

Shift-click, or double-click
Open the clip in the Source Monitor with that use already set as in and out.

Alt-click
Copy the clip's name, ready to paste into the Project panel's search box. Premiere has no reveal-in-project command for a panel to call.

If something doesn't go to plan

The four things that go wrong

Trace isn't in the Window menu.
Look under Window > UXP Plugins, not Window > Extensions. If UXP Plugins is not there at all, Premiere is older than 25.6 — check Premiere Pro > About Premiere Pro.

Double-clicking the .ccx did nothing.
Open Creative Cloud Desktop first, then double-click the file again. The installer is part of Creative Cloud, so it has to be running.

It says 0 uses and I know I used that clip.
Three honest causes: the clip is used via a subclip or a second import of the same file (Trace matches those by media file, and says so on the row); the sequence is filtered out by Hide old cuts; or the project was changed outside Premiere. Press the re-scan button at the bottom right.

The panel is too small to read.
Trace has three layouts and picks one from the space it is given. Make it a little wider and the duration column comes back; a little taller and the summary block returns.

What Trace deliberately will not do

It never moves, renames or deletes anything. Markers and in/out points are the most it will ever change, and both are one undo away. It reads your project and nothing else — no account, no upload, no telemetry. The only thing it fetches is a small file saying whether a newer version exists.

Still stuck?

Email support@nkcourses.co.uk, or reply to your receipt. I'm one person, so it might take a day — but it will be me answering.

Full documentation: www.nkcourses.co.uk/trace/help

There is also Trace+

Trace scans a clip. Trace+ scans the entire project — which media the project is not using, and what your archive would weigh without it. It installs alongside this one and replaces nothing.
